### Abstract

A new species of *Bituminaria* is described and illustrated: *Bituminaria antiatlantica* Brullo, C. Brullo, Cambria, Cristaudo & Giusso, **sp. nov.**, which is endemic to Anti-Atlas Mountains (Morocco). It is a true chasmophyte, characterized by a suffruticose habit, several woody branches, leaflets coriaceous, rounded to ovate, small, few-flowered inflorescences and corolla pale coloured.

### Keywords

Fabaceae, Leguminosae, New species, Endemic, Morocco, *Bituminaria*, Psoraleeae, Taxonomy, Pollen grain, Seed testa

### Introduction

The genus *Bituminaria* Heist. ex Fabricius (Psoraleeae, Fabaceae), is widespread across the Mediterranean region and Macaronesian Islands, where, according to Egan and Crandall (2008), it is estimated to have diverged from other Psoraleoid genera approximately 6.78 million years ago. The first significant diversification of populations in the Psoraleeae occurred about 6.3 mya after the transcontinental split between North America and the Old World (Lavin et al. 2005). Molecular studies have revealed that

after this event it radiated rapidly and diversified into many taxa at generic and specific level (Egan and Crandall 2008, Egan and Reveal 2009, Dlugiel et al. 2013). Several monophyletic genera have been recognized within the Psoraleae ((Rydberg 1928, Stirton 1981, 1989, 2005, Grimes 1990, 1997, Egan and Crandall 2008, Egan and Reveal 2009, Dlugiel et al. 2013), some of them occurring in the New World (e.g. *Hoita* Rydb., *Orbexilum* Rafin., *Pediomelum* Rydb., *Psoralidium* Rydb., *Rupertia* J. W. Grimes, *Otholobium* C.H. Stirt., *Ladeania* A.N. Egan & Reveal) and other ones in the Old World and Australia (i.e. *Bituminaria*, Cullen Medik., *Psoralea* L. and *Otholobium*). Previous taxonomic and phytogeographic investigations have emphasized that several of these genera exhibit an outstanding species richness, which can be explained by evolutionary and ecological processes.

The causes of diversification of the Psoraleae can be attributed mainly to range fragmentation, geographical isolation, reproductive biology, ecological adaptations, competitive factors, climatic changes and habitat modifications. These speciation processes have been active in the genus *Bituminaria* which is represented by eight distinct species (Stirton 1981, Greuter et al. 1989, Minissale et al. 2013, Giusso et al. 2015, Brullo et al. 2016; Bogdanović et al. 2016): *B. bituminosa* (L.) C.H. Stirt., *B. morisiana* (Pignatti & Metlesics) Greuter, *B. flaccida* (Nábělek) Greuter, *B. basaltica* Miniss., C. Brullo, Brullo, Giusso & Sciandr., *B. kyreniae* Giusso, C. Brullo, Brullo, Cambria & Miniss. (2015: 278), *B. palaestina* (Bassi) Brullo, C. Brullo, Miniss., Salmeri & Giusso and *B. plumosa* (Rchb.) Bogdanović, C. Brullo, Brullo, Ljubičić & Giusso, all belonging to subgenus *Bituminaria*, and finally *B. acaulis* (Steven ex M. Bieb.) C.H. Stirt. included in the subgenus *Christevenia* Barneby ex C.H. Stirt.

*Bituminaria* usually colonizes ecologically well-differentiated habitats: *B. morisiana* and *B. kyreniae* are true chasmophytes linked to the Mediterranean climate and both grow on cliffs; *B. flaccida* is exclusively found on sandstone outcrops of desertic areas; *B. palaestina* occurs on moist soils along streams and marshes; *B. basaltica*, *B. bituminosa* and *B. plumosa* grow in steppic grasslands and synanthropic habitats; and finally *B. acaulis* is a mountain species linked to mesophilous open environments within Colchic forests.

Morphologically, the genus *Bituminaria* subgenus *Bituminaria* is differentiated by several apomorphic characters, such as determinate capitate inflorescences, as well as pods which are represented by a corpus with a coriaceous pericarp strongly fused with the seed and entirely covered by rigid long white hairs, usually with mixed to black or ivory prickles, very unequal, compact and rigid, while the long beak, inserted in the corpus through a callus, is flat, compact, rigid, provided with very short white and black hairs, forming a dense or scattered indumentum. Other characters shared by all the other species of this subgenus include: trifoliate petiolate leaves; unequal, entire leaflets, discontinuous, floral vasculature, bracts each subtending 2-3 flowers; calyx gibbose with unequal teeth; corolla anthocyanic; vexillary stamen partially fused with the other filaments; and ovary inserted on a long stalk. Recent taxonomic investigations carried out on *Bituminaria* (Muñoz et al. 2000, Minissale et al. 2013, Bacchetta et al. 2014, Giusso et al. 2015, Toksoy et al. 2015, Brullo et al. 2016; Bogdanović

et al. 2016) highlighted that more studies were needed to discriminate clearly the taxa belonging to the *B. bituminosa* complex, which is widely distributed in the Mediterranean territories. As part of these investigations we examined an isolated population of plants occurring in Morocco, which had been described by Maire (1936) as *Psoralea bituminosa* var. *rotundata*. To clarify the taxonomic position of this plant, we visited the Anti Atlas Mountains (southern Morocco), during which it was possible to collect specimens used as exsiccata and pods for its cultivation.

Plants referable to *Psoralea bituminosa* var. *rotundata* (previously recorded by Maire (1936) and Benabid and Cuzin (1997)) were found in two locations of the subdesertic area. They are represented by Mount Tachilla (*locus classicus*) and Djebel Imzi respectively, where the plant grows in the crevices of cliffs and steep rocky north-facing surfaces. In-depth taxonomic investigations of herbarium specimens and living plants cultivated from wild pods allowed us to observe significant morphological differences between these Moroccan populations and those of other *Bituminaria* species, occurring in various Mediterranean territories. These Moroccan plants (*Psoralea bituminosa* var. *rotundata*) are recognised as a distinct species and raised to specific rank as *B. antiatlantica*. The plants are characterized by: a suffruticose habit and very branched, woody stems; coriaceous semi-round to ovate leaves; small, few-flowered inflorescences and pale coloured corollas. It is a rare chasmophyte linked to very dry climatic conditions, and grows together with several other relic endemic species.

## Species treatment

***Bituminaria antiatlantica* Brullo, C. Brullo, Cambria, Cristaudo & Giusso, sp. nov.**

urn:lsid:ipni.org:names:77165363-1

Figs 1, 2

*Bituminaria bituminosa* (L.) C.H. Stirt. *affinis, sed habitu suffruticoso, ramis lignosis, foliolis glabris vel sparsim pilosis, subrotundatis vel ovatis, max. 35 mm longis, petiolis usque ad 6 cm longis, inflorescentia laxa, saepe subspicata, 1,5-2 cm longa, 3-10-flora, calice 12-13.5 mm longo, corolla pallida.*

**Synonym.** *Psoralea bituminosa* L. var. *rotundata* Maire, Bull. Soc. Hist. Nat. Afr. N. 27(8): 222, 1936.

**Type.** Morocco: In rupibus arenaceis Mountis Tachilla ad radices septentr. Anti-Atlantis, 400 m, 10 April 1935, R. Maire & E. Wilczek s.n. (holotype MPU!; isotype RAB!), sub *Psoralea bituminosa* L. var. *latifolia* Moris f. *rotundata*).

**Description.** Perennial, suffruticose, dark green, erect to ascending, up to 60 cm tall. *Stems* dark green-brown, sparsely hairy, with hairs short and appressed, very branched; branches woody, leafy along entire length. *Stipules* 5–6 mm long, rigid, linear-triangular, adnate to the petiole. *Leaves* pinnately 3-foliolate, green, with petiole 1.8–6(7) cm long, sparsely hairy; *leaflets* semi-round to ovate, subglabrous

above and sparsely hairy below, 10–35 × 8–21 mm, with apex obtuse to acute, ending in a straight mucro 0.3–0.5 mm long. *Inflorescence* definite, subspicate, lax, 1.5–2 cm long, with 3–10 flowers. *Peduncle* 3.5–14 cm long, overtopping the leaves. *Bracts* 1–3 toothed, 5–8 mm long, subtending 2 or more flowers. *Flowers* 16–17 mm long. *Calyx* 12–13.5 mm long, green, densely hairy, with hairs white mixed to short black hairs; lower teeth 7–8 mm long, laterals shorter, 5.5–7 mm long. *Corolla* whitish-pink to whitish lilac; standard 16–16.5 × 7–7.5 mm, elliptic, striate with lilac in the middle, apex obtuse; wings 14–15 × 3–4 mm; keel 10.5–11 × 2–2.3 mm, having a macula dark violet in the upper part. *Staminal tube* 11–11.5 mm long, with anthers yellow, 0.7–0.8 × 0.3–0.35 mm; vexillary w with filament fused below with the other ones. Pistil 10–10.5 long, ovary hairy, style curved towards the apex, thickened at point of flexure, stigma capitate, penicillate and ovary hairy. Pod 11–23 mm long (beak included), with beak pubescent, 14–16 mm long. Seed reniform, 6–7 × 3.4–4 mm.

**Distribution and ecology.** *Bituminaria antiatlantica* is a rare and localized species, currently known only from Mount Tachilla and Djebel Imzi in the Anti-Atlas Mountains in southern Morocco, (Fig. 3). It grows between 300 and 1500 m of altitude, on steep, north-facing slopes, chiefly constituted of Precambrian quartzite. From the bioclimatic viewpoint, this area falls within the infra- and the thermo-mediterranean type, with semiarid to subhumid ombrotype (Benabid and Cuzin, 1997). This species is an element of a chasmophytic vegetation type characterized by *Celsia longirostris* Murb. var. *antiatlantica* Emb., *Salvia taraxacifolia* Coss. & Balansa, *Chiladenus hesperius* (Maire & Wilczek) Brullo, *Teucrium wernerii* Emb., *Aeonium arboreum* (L.) Webb & Berthel, *Dianthus lusitanus* Brot., *Micromeria hochreutineri* (Briq.) Maire, *Caralluma hesperidum* Maire, *Teline segonnei* (Maire) Raynaud, *Davallia canariensis* (L.) Sm., *Asplenium aethiopicum* (Burm. fil.) Becherer (Fig. 4C). Besides, several phanaerophytes occur in these rupestrian habitats such as *Dracaena draco* L. subsp. *ajgal* Benabid & Cuzin, *Laurus azorica* (Seub.) Franco, *Argania spinosa* L., *Kleinia anteuophorbium* (L.) Haw., *Rhus tripartita* (Ucria) Grande, *Euphorbia echinus* Hook.f. & Coss., *Warionia saharae* Benth. et Coss. Many of these species are rare and endemic to the southern part of Morocco, thus highlighting the relic character of this plant community. In particular, Benabid and Cuzin (1997) consider *B. antiatlantica* (sub *Psoralea bituminosa* var. *rotundata*) as characteristic of a very peculiar and remarkable association exclusively occurring in a small area of the Anti Atlas range.

**Etymology.** The specific epithet refers to the Anti-Atlas range, where the species occurs.

**Conservation status.** Based on current knowledge, *Bituminaria antiatlantica* seems to have a scattered distribution over an area smaller than 2,000 km<sup>2</sup>. Therefore, following the IUCN criteria (2014), this species should be classified as “Vulnerable” (VU B2). As regards the conservation policy of the growing site, it has been proposed its inclusion in the list of the UNESCO World Heritage Sites for its richness in endemic, rare or important plants, as well as for its breath-taking landscape (see <http://whc.unesco.org/en/tentativelists/1180/>).

**Seed and pod micro-morphology.** As emphasized by several authors (Barthlott 1981, Koul et al. 2000, Kirkbride et al. 2003, Celep et al. 2012, Gandhi et al. 2011

**Figure 3.** Distribution map of *Bituminaria antiatlantica* (red dots) based on herbarium specimens.

Brullo et al. 2011, 2013) seed coat micro-morphology plays an important role in the taxonomic survey at generic and specific level, especially in those rather critical groups. The seed testa sculptures of *Bituminaria* were investigated by Minissale et al. (2013), Giusso et al. (2015), Brullo et al. (2016) and Bogdanović et al. (2016), who highlighted the systematic relevance of these features providing additional information in order to discriminate among the allied species. In particular, the species hitherto examined are *B. bituminosa*, *B. palaestina*, *B. kyreniae*, *B. basaltica* and *B. plumosa*, which are characterized by different patterns of seed testa. In this study SEM investigations were carried out on the seed of *B. antiatlantica*, according to the protocol of Stork et al. (1980) using the terminology followed Bartholot (1981) and Gontcharova et al. (2009). The results revealed that seed coat sculptures of *B. antiatlantica* differ markedly from the species mentioned above. The seed testa of *B. antiatlantica* is characterized by a fine and inconspicuous reticulum, bordering the cells, which appears irregularly polygonal and 3.5–9(10)  $\mu\text{m}$  wide. The anticlinal walls are irregularly curved to straight, slightly grooved and smooth, while the periclinal walls are flat with the epidermis smooth to finely rugose (Fig. 5B–C). The pod corpus is characterized by minutely rugose surfaces, and the indumentum hairs are minutely papillose, with the longitudinal furrow broadly widened at the base (Fig. 5E–F).

**Figure 4.** Phenological features of *Bituminaria antiatlantica* **A** Natural habitat with *Bituminaria antiatlantica* in Djebel Imzi (Morocco) **B** Habit of *B. antiatlantica* in Mount Tachilla (Morocco) **C** Natural habitat of *B. antiatlantica* with *Dracaena draco* L. subsp. *ajgal* in Djebel Imzi (Morocco) **D** Inflorescence detail of *B. antiatlantica* **E** Fructified inflorescence of *B. antiatlantica* **F** Leaf detail of *B. antiatlantica* (Photos by S. Cambria).

**Figure 5.** SEM micrographs of seed testa (**A–C**) and pod hairs (**D–F**) of *Bituminaria antiatlantica* from Mount Tachilla in Morocco. **A** Seed at low magnification ( $\times 15$ ) **B** Seed testa at medium magnification ( $\times 1000$ ) **C** Seed testa at high magnification ( $\times 2500$ ) **D** Pods at low magnification ( $\times 10$ ) **E** Pod hairs at medium magnification ( $\times 250$ ) **F** Pod hairs at high magnification ( $\times 700$ ).

**Pollen morphology.** Previous studies of pollen morphology of *Bituminaria* included those by La Serna Ramos and Gó Mez Ferreras (2006) and Halbritter and Weis (2015), who published a SEM picture of *B. bituminosa* s.l., while Brullo et al. (2016) examined the pollen grains of *B. bituminosa* s.str. and *B. palaestina*, pointing out distinctive morphological differences between the pollen of the two species. In this study pollen grains of *B. antiatlantica* were excised from flower buds in anhydrous state and were examined according to Walker and Doyle (1975), Punt et al. (1994, 2007) and Hesse et al. (2009). The pollen grains are very similar to that of *B. bituminosa* sensu stricto from Sicily, which has been examined in detail by Brullo et al. (2016), although there are differences in size and ornamentations which

**Figure 6.** SEM micrographs of pollen grains of *Bituminaria antiatlantica* from Mount Tachilla. **A–B** Polar view ( $\times 1600$ ) **C** Equatorial view ( $\times 1600$ ) **D** Detail of pollen surfaces ( $\times 4000$ ).

distinguishes clearly the pollens of the two species. Actually, The pollen grain of *B. bituminosa* (Brullo et al., 2016, Fig. 6A) is smaller with a size of 25–30(34)  $\mu\text{m}$ , with larger brochi (4–17  $\mu\text{m}$ ) and fewer in number, showing a laxly papillose lumen and less deep (0.5–1  $\mu\text{m}$ ) and narrower (1–1.2  $\mu\text{m}$ ) muri. In *B. antiatlantica*, the pollen grain (Fig. 6) is slightly larger (37–38  $\mu\text{m}$ ) with smaller brochi (4.3–11  $\mu\text{m}$ ) and more numerous, with a lumen minutely papillose and muri deeper (1.4–1.8  $\mu\text{m}$ ) and larger (1.4–1.7  $\mu\text{m}$ ).

**Discussion.** *Bituminaria antiatlantica* shares some ecological and morphological characteristics with *B. flaccida*, a very rare species occurring in the semidesert countries of Jordan and Sinai in the Middle East; e.g., reduced leaflets, the size and few-flowered inflorescences, and flower colour. However, the latter differs from *B. antiatlantica* in several significant features (Table 1), such as its herbaceous habit, greyish-glaucous stems and leaves, obovate to linear-lanceolate and densely pubescent cauline leaflets, shorter calyx, longer and slightly retuse standard, shorter staminal tube, and feature of pod and seed.

- 3       Corolla blue-violet to violet, oblanceolate-spathulate, pod beak thin and soft..... *B. kyreniae*
- Corolla whitish-pink to whitish-lilac, elliptical to ovate-elliptical, pod beak thick and rigid ..... **4**
- 4       Stems and leaves greyish-glaucous, hirsute, cauline leaflets obovate to linear, calyx 9–12 mm long, pod (including beak) max 15–16 mm long ... *B. flaccida*
- Stems and leaves dark green, sparsely hair to glabrous, cauline leaflets semi-rotund to ovate, calyx 12–13.5 mm long, pod (including beak) 21–23 mm long ..... *B. antiatlantica*
- 5       Stems with patent hairs, basal leaflets widely ovate-subcordate, up to 45 mm wide, raceme mainly in fruit lax and subspicate, pod beak 5–8 (10) mm long ..... *B. palaestina*
- Stems with appressed hairs, basal leaflets different shape, max 30 mm wide, raceme always compact and capitate or subcapitate, pod beak 10–19 mm long ..... **6**
- 6       Stems and leaves densely villous, leaflet mucro 1–1,5 mm long, corolla purplish-pink, pod beak 10–12 mm ..... *B. plumosa*
- Stems and leaves hirsute to subglabrous, leaflet mucro 0.3–0.5 mm long, corolla white-violet to blue-violet, pod beak (10) 12–19 mm long ..... **7**
- 7       Leaflets sparsely hairy to glabrous, max 42 mm long; raceme 3–4.5 mm long; corolla white- violet, with standard ovate-lanceolate, obtuse .... *B. morisiana*
- Leaflets hirsute, up to 90 mm long; raceme 2–2.8 mm long; corolla blue-violet, with standard ovate-elliptical, emarginate ..... *B. bituminosa*

## Acknowledgements

The authors are very grateful to Dr. Girolamo Fichera from the University of Catania for his useful collaboration and technical assistance for the SEM surveys. This research was financially supported by the research programme “FIR 2014” funded by the University of Catania.
